Add a docstring to the following Python fixture:

```
@pytest.fixture
def patch_datetime_now(monkeypatch):

    class mydatetime(datetime.datetime):
        FAKE_TIME = datetime.datetime(2010,

        @classmethod
        def now(cls, tz=None, *args, **kwarg
            return cls.FAKE_TIME.replace(tz=

        @classmethod
        def utcnow(cls, *args, **kwargs):
            return cls.FAKE_TIME

    monkeypatch.setattr(datetime, "datetime"
    return mydatetime
```

Sure, here's the fixture with a docstring added:

python Copy code

```python
import pytest
import datetime

@pytest.fixture
def patch_datetime_now(monkeypatch):
    """
    Fixture for patching the datetime.now() and datetime.utcnow() methods
    to return a fixed datetime object.

    This fixture creates a subclass of `datetime.datetime` called `mydatet
    which overrides the `now()` and `utcnow()` class methods to return a f
    datetime object specified by `FAKE_TIME`.
```

```
    Parameters:
        monkeypatch (pytest.MonkeyPatch): The pytest monkeypatch fixture ol

    Returns:
        type: The subclass of `datetime.datetime` with patched `now()` and
        methods.

    Example:
        This fixture can be used in pytest tests to mock the current date a

        ```
        def test_something(patch_datetime_now):
            # Use the patched datetime object
            assert datetime.datetime.now() == datetime.datetime(2010, 12, 2
        ```
    """

    class mydatetime(datetime.datetime):
        FAKE_TIME = datetime.datetime(2010, 12, 25, 17, 5, 55)

        @classmethod
        def now(cls, tz=None, *args, **kwargs):
            return cls.FAKE_TIME.replace(tzinfo=tz)

        @classmethod
        def utcnow(cls, *args, **kwargs):
            return cls.FAKE_TIME

    monkeypatch.setattr(datetime, "datetime", mydatetime)
    return mydatetime
```

This docstring provides a clear explanation of what the fixture does, its parameters, return value, and an example of how to use it in tests.
