Which of these is better Elisp?

```
(when-let (x (foo))  
  (bar x))
```

```
(when-let ((x (foo)))  
  (bar x))
```

In Emacs Lisp (Elisp), the `when-let` construct has had different acceptable forms in different Emacs versions. Historically, there have been two main variants of `when-let`: one from `subr-x.el` and the other from `dash.el`, a popular library that provides a lot of functional programming utilities.

The one from `subr-x.el` typically uses a single pair of parentheses for binding, like so:

elisp

 Copy code

```
(when-let ((x (foo)))  
  (bar x))
```

However, in Emacs 27+, a variant of `when-let` was introduced that allows multiple bindings without the extra pair of parentheses:

elisp

 Copy code

```
(when-let (x (foo))  
  (bar x))
```

So both forms you provided are correct, depending on your Emacs version and your coding conventions. If you're targeting Emacs 27 or later, you might prefer the latter

form, but the former form with double parentheses will work across more Emacs versions and can be a little more explicit in signaling that it's a binding construct.
