In CSS (and maybe with Tailwind CSS), is it a good practice to always use `rem` even for very small values, such as `0.075rem` instead of `1.2px`? Specifying like `0.075rem` looks a bit weird to me.

In CSS, whether to use `rem` or `px` for small values depends on the context and the goals of your design. The use of `rem` (root em) is often recommended for responsive and accessible design because it allows for better scaling with user settings, especially in terms of font size and layout spacing. `rem` units are relative to the root element (`html`), making them more flexible when the user changes their browser's default font size.

However, for very small values, like `0.075rem` (which is equivalent to approximately `1.2px` if the root font size is `16px`), it might not be practical to use `rem` for several reasons:

- 1. Precision and Clarity:** Such small `rem` values can make the code less readable and harder to understand at a glance. It's often easier to conceptualize and work with small values in pixels (`px`).
- 2. Rendering Differences:** At such small sizes, different browsers and devices might render `rem` values slightly differently, potentially leading to inconsistencies in design.
- 3. Use Case Specificity:** For very fine adjustments, like borders, shadows, or small spacing, using `px` might offer more control and consistency across devices.
- 4. Performance:** While the performance difference is negligible, `px` values are straightforward for browsers to calculate and render.

In summary, while `rem` is generally good for responsive and accessible design, for very small values, you might find it more practical to use `px` . It's important to consider the specific needs of your project and the potential impact on readability, consistency, and control over the design.

In Tailwind CSS, which is utility-first, you often have predefined classes for margins, paddings, font sizes, etc., in `rem` values. However, Tailwind also allows for customization

where you can define specific values, in either `rem` or `px` , based on your design requirements.

Remember, the best practice is what works best for your specific project and audience needs, balancing responsiveness and accessibility with practicality and clarity.
