If I create a temporary file by Python `tempfile.NamedTemporaryFile`, what is the access permission (for example whether I can execute this file)?

When you create a temporary file using `tempfile.NamedTemporaryFile` in Python, the default access permissions are typically set to allow reading and writing by the user who created the file, but not execution. In most environments, the file permissions are set to `'rw-----'` (octal `0o600`), which means only the user who created the file has the permission to read and write the file, and there are no permissions for group or others.

If you need to execute the file, you would have to manually change the file permissions using Python's `os.chmod` function or a similar method. However, it's important to consider the security implications of making a temporary file executable, especially if the contents of the file are not completely under your control or if the file is being used in a shared or insecure environment.
