easiest way to see the network calls a server or my computer made

If you want to see the network calls made by your server or computer, there are various tools and methods you can use depending on your specific requirements and the level of detail you desire. Here are some ways to monitor network activity:

1. Command Line Tools:

- **Windows:**
 - **netstat:** A built-in tool that provides information about network connections. Using `netstat -an` will give you a list of current connections.
- **Linux/macOS:**
 - **netstat:** Similar to Windows but might require installation on some systems.
 - **ss:** A utility to investigate sockets.
 - **iftop:** Displays bandwidth usage on an interface by host.
 - **tcpdump:** A powerful command-line packet analyzer.
- Example command with tcpdump: `tcpdump -i eth0` (monitors all traffic on the eth0 interface).

2. Graphical Tools:

- **Windows:**
 - **Resource Monitor:** Built into Windows, provides a way to track network activity.
 - **Wireshark:** A popular, free network protocol analyzer that can capture and display the details of network traffic.
- **Linux/macOS:**
 - **Wireshark:** As mentioned above.
 - **nload:** Displays network traffic of an interface.

3. Web Browsers:

- If you're specifically interested in network calls made by websites (HTTP requests/responses), browser developer tools offer network tabs that display this info.
 - **Chrome/Firefox/Edge:** Right-click on a web page, select "Inspect" or "Inspect Element", and then go to the "Network" tab.

4. Firewalls & Security Solutions:

- Many firewalls and security solutions allow you to inspect traffic that passes through them. Examples include:
 - **Windows Firewall**
 - **ufw** or **iptables** on Linux
 - Commercial solutions like Palo Alto Networks or Fortinet

5. Router or Network Device Monitoring:

- Some advanced routers or switches have features to monitor the network traffic that passes through them. Look for features like traffic analysis, packet capture, or logging.

6. Cloud Monitoring Solutions:

- If you're working in a cloud environment (like AWS, Azure, or GCP), they often offer native tools to monitor network traffic to/from your virtual servers.

Remember, when monitoring network traffic, ensure that you have the necessary permissions and that you respect privacy considerations. Intercepting or monitoring traffic without appropriate permissions can be illegal or against terms of service.
