transifex github integration sync goes both ways?

As of my last update in September 2021, Transifex provided a GitHub integration that allowed for synchronization of source and translation files between a Transifex project and a GitHub repository. Here's how it generally worked:

- 1. Push from GitHub to Transifex:** When you updated source files (like `.po` or `.json` files) in your GitHub repository, those changes could be automatically reflected in your Transifex project. This meant that new strings or updated strings in your source files would be available for translation in Transifex.
- 2. Pull from Transifex to GitHub:** Translated files from Transifex could be pulled into your GitHub repository, either manually or on a schedule. This allowed you to keep your repository updated with the latest translations from Transifex.

So, yes, the integration was bidirectional – changes in the GitHub repo could be reflected in Transifex, and translations in Transifex could be reflected back in the GitHub repo. However, it's essential to understand the workflow and set it up correctly to avoid overwriting or losing data.

If there have been any changes or updates to this integration after September 2021, I would recommend checking Transifex's official documentation or their support resources for the most up-to-date information.
