how can the following documentation be improved

Available Categorization AI Models

When using `build_categorization_ai_pipeline`, you can select which Image Module and/or Text Module to use for

classification. At least one between the Image Model or the Text Model must be specified. Both can also be used at the same time.

The list of available Categorization Models is implemented as an Enum containing the following elements:

```
.. literalinclude::
```

```
/sdk/boilerplates/test_document_categorization.py
```

```
:language: python
```

```
:start-after: Start Models
```

```
:end-before: End Models
```

```
:dedent: 4
```

Categorization AI Models Available

`build_categorization_ai_pipeline` is a function that offers you the ability to define the categorization strategy you desire by allowing the selection of either an Image Module, a Text Module, or a combination of both for classification tasks.

It is crucial to note that you must specify at least one of the Image Model or the Text Model. However, for more comprehensive categorization, you can also opt to use both concurrently.

We provide a list of available Categorization Models within our Enum construct. The elements within this list are as follows:

You can find the complete code snippet in

`/sdk/boilerplates/test_document_categorization.py`. We have included the relevant part of this script for your convenience below:

python

 Copy code

```
# Make sure to replace `...` with the actual code snippet  
# Start Models  
...  
# End Models
```

The language used for this model list is Python. Please ensure that you adjust the indentation by four spaces (dedent by 4) to properly align with your existing code structure.

what can be improved further?

Overall, the revised documentation is quite clear and well-structured. However, there are a few areas where it could be further enhanced to provide additional clarity or context to users.

- 1. Specify Required and Optional Parameters Clearly:** The function, `build_categorization_ai_pipeline`, should clearly describe what each parameter represents, its datatype, and whether it's required or optional. This could be presented in a tabular format for better readability.
- 2. Example Usage:** Provide a simple code example demonstrating how to use `build_categorization_ai_pipeline` with different parameters.
- 3. Explain Enum Use:** While you mention that the list of models is implemented as an Enum, it might be helpful to briefly describe what an Enum is and why it is used in this context, especially for less experienced programmers.
- 4. Provide More Details on Models:** You might want to give more context about the Image Model and Text Model. For instance, explain when one might prefer to use one over the other, or both together. What are the advantages or limitations of each? This would provide the user with a better understanding of how to effectively use these models.
- 5. Better Code Display:** Use a better method to display the actual code snippet from the Python file. The `...` placeholder doesn't give a clear idea of what the code

looks like. If it's not feasible to include the whole code snippet in the documentation, consider providing a link to the source code file on your repository.

Here's an improved version of the documentation, keeping the above points in mind:

Available Categorization AI Models

The `build_categorization_ai_pipeline` function allows you to select which classification model to use. This could be an Image Module, a Text Module, or both.

Parameters:

- `Image Module` (optional): This parameter allows you to use an image-based classification model. The available models are listed in the Image Models Enum.
- `Text Module` (optional): This parameter allows you to use a text-based classification model. The available models are listed in the Text Models Enum.

Note: At least one of the Image or Text Model parameters must be specified.

Example usage:

python

 Copy code

```
build_categorization_ai_pipeline(ImageModule='ModelA', TextModule='ModelB')
```

In this code snippet, 'ModelA' and 'ModelB' are enum values representing the specific Image and Text models, respectively.

The list of available Categorization Models can be found in an Enum in the `/sdk/boilerplates/test_document_categorization.py` file. An Enum, or enumerated type, is a data type that consists of a set of named values. We've used it here for easy reference to different categorization models.

python

 Copy code

```
# Start Models Enum  
...  
# End Models Enum
```

Please replace `...` with the actual code snippet, and remember to adjust the indentation by four spaces (dedent by 4) to align it properly with your code structure.

The Image Module is best used when the data to be categorized includes images, while the Text Module is suited for text-based data. If your data contains both text and images, it could be beneficial to use both modules for a more comprehensive categorization.

You can review the source code file in our repository [here ↗](#). (Replace # with actual URL)
