#Using the Force formula $F=ma$

```
while True:
    mass = int(input("Enter the mass value: "))
    if mass > 0:
        break
while True:
    acceleration = int(input("Enter the acceleration: "))
    if acceleration > 0:
        break
print("The Force is", mass * acceleration)
- Can you make it so instead of using 2 while loops to
complete this, it instead uses 1
```

Certainly! You can combine the two input validations into a single while loop. Here's the modified code:

python

 Copy code

```
while True:
    mass = int(input("Enter the mass value: "))
    acceleration = int(input("Enter the acceleration: "))

    if mass > 0 and acceleration > 0:
        break

print("The Force is", mass * acceleration)
```

This way, the program will continue to prompt the user for input until both the mass and acceleration are greater than 0. Once the conditions are met, it will break out of the loop and calculate the force.
